

Where spurious sharpening forms

Entry-state boundary coloured by posterior ratio p (dark = best determined). $\times$ = final sharpest point; $\circ$ = entry sharpest point.

Pointwise-sensitivity prediction refuted (sites at the 38th–68th percentile). p puts every site in its best-determined 10%, but p tracks the entry curvature (Spearman -0.63 to -0.79) and also flags fresh A's true feature: sharp features grow where the entry shape is already most curved.
